

Space X Falcon 9 First Stage Landing Prediction

Assignment: Machine Learning Prediction

Estimated time needed: 60 minutes

Space X advertises Falcon 9 rocket launches on its website with a cost of 62 million dollars; other providers cost upward of 165 million dollars each, much of the savings is because Space X can reuse the first stage. Therefore if we can determine if the first stage will land, we can determine the cost of a launch. This information can be used if an alternate company wants to bid against space X for a rocket launch. In this lab, you will create a machine learning pipeline to predict if the first stage will land given the data from the preceding labs.

Several examples of an unsuccessful landing are shown here:

Most unsuccessful landings are planed. Space X; performs a controlled landing in the oceans.

Objectives

Perform exploratory Data Analysis and determine Training Labels

- create a column for the class
- Standardize the data
- Split into training data and test data
- -Find best Hyperparameter for SVM, Classification Trees and Logistic Regression
 - Find the method performs best using test data

Import Libraries and Define Auxiliary Functions

```
In [ ]: # import piplite
# await piplite.install(['numpy'])
# await piplite.install(['pandas'])
# await piplite.install(['seaborn'])
```

We will import the following libraries for the lab

```
In []: # Pandas is a software library written for the Python programming language for d
import pandas as pd
# NumPy is a library for the Python programming language, adding support for lar
import numpy as np
# Matplotlib is a plotting library for python and pyplot gives us a MatLab like
import matplotlib.pyplot as plt
#Seaborn is a Python data visualization library based on matplotlib. It provides
import seaborn as sns
# Preprocessing allows us to standarsize our data
from sklearn import preprocessing
# Allows us to split our data into training and testing data
from sklearn.model_selection import train_test_split
# Allows us to test parameters of classification algorithms and find the best on
from sklearn.model_selection import GridSearchCV
# Logistic Regression classification algorithm
```

```
from sklearn.linear_model import LogisticRegression
# Support Vector Machine classification algorithm
from sklearn.svm import SVC
# Decision Tree classification algorithm
from sklearn.tree import DecisionTreeClassifier
# K Nearest Neighbors classification algorithm
from sklearn.neighbors import KNeighborsClassifier
from sklearn.metrics import confusion_matrix, accuracy_score
import warnings
warnings.simplefilter('ignore')
```

```
In [ ]: model_performance = {}
```

This function is to plot the confusion matrix.

Load the dataframe

Load the data

```
In []: # from js import fetch
import io

URL1 = "https://cf-courses-data.s3.us.cloud-object-storage.appdomain.cloud/IBM-D
# resp1 = await fetch(URL1)
# text1 = io.BytesIO((await resp1.arrayBuffer()).to_py())
data = pd.read_csv(URL1)
In []: data.head()
```

Out[]:	FlightNur	nber	Date Boost	erVersion	PayloadM	ass Orbit	LaunchSite	Outcome	Fli

TASK 1

Create a NumPy array from the column Class in data, by applying the method to_numpy() then assign it to the variable Y, make sure the output is a Pandas series (only one bracket df['name of column']).

```
In [ ]: Y = data['Class'].to_numpy()
```

TASK 2

Standardize the data in X then reassign it to the variable X using the transform provided below.

```
In [ ]: # students get this
    transform = preprocessing.StandardScaler()
    X = transform.fit_transform(X)
```

We split the data into training and testing data using the function train_test_split. The training data is divided into validation data, a second set used for training data; then the models are trained and hyperparameters are selected using the function GridSearchCV.

TASK 3

Use the function train_test_split to split the data X and Y into training and test data. Set the parameter test_size to 0.2 and random_state to 2. The training data and test data should be assigned to the following labels.

```
X_train, X_test, Y_train, Y_test
```

```
In [ ]: X_train, X_test, Y_train, Y_test = train_test_split(X, Y, test_size=0.2, random_
we can see we only have 18 test samples.
```

```
In [ ]: Y_test.shape
Out[ ]: (18,)
```

TASK 4

Create a logistic regression object then create a GridSearchCV object logreg_cv with cv = 10. Fit the object to find the best parameters from the dictionary parameters.

We output the <code>GridSearchCV</code> object for logistic regression. We display the best parameters using the data attribute <code>best_params_</code> and the accuracy on the validation data using the data attribute <code>best_score_</code>.

```
In [ ]: print("tuned hpyerparameters :(best parameters) ",logreg_cv.best_params_)
    print("accuracy :",logreg_cv.best_score_)

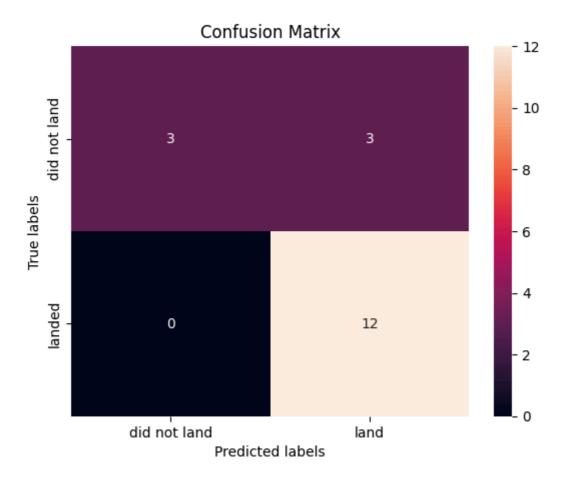

model_performance['logreg'] = logreg_cv.best_score_

tuned hpyerparameters :(best parameters) {'C': 0.01, 'penalty': '12', 'solver': 'lbfgs'}
accuracy : 0.8464285714285713
```

TASK 5

Calculate the accuracy on the test data using the method score:

plot confusion matrix(Y test,yhat)

Examining the confusion matrix, we see that logistic regression can distinguish between the different classes. We see that the major problem is false positives.

TASK 6

Create a support vector machine object then create a <code>GridSearchCV</code> object <code>svm_cv</code> with <code>cv</code> - 10. Fit the object to find the best parameters from the dictionary <code>parameters</code> .

```
tuned hpyerparameters :(best parameters) {'C': 1.0, 'gamma': 0.0316227766016837
9, 'kernel': 'sigmoid'}
accuracy : 0.8482142857142856
```

TASK 7

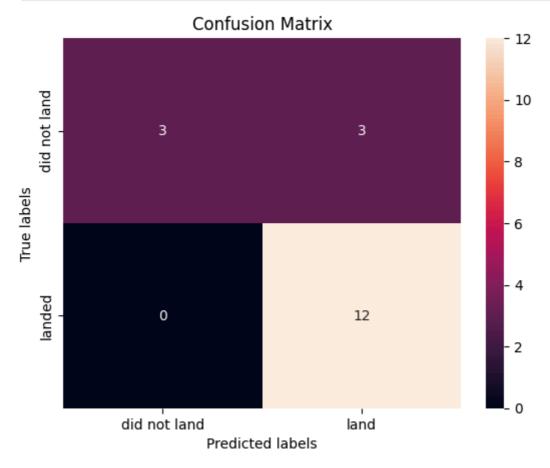

Calculate the accuracy on the test data using the method score:

```
In [ ]: svm = SVC(**svm_cv.best_params_)
    svm.fit(X_train, Y_train)
    svm.score(X_test, Y_test)
```

Out[]: 0.83333333333333334

We can plot the confusion matrix

```
In [ ]: yhat=svm.predict(X_test)
plot_confusion_matrix(Y_test,yhat)
```

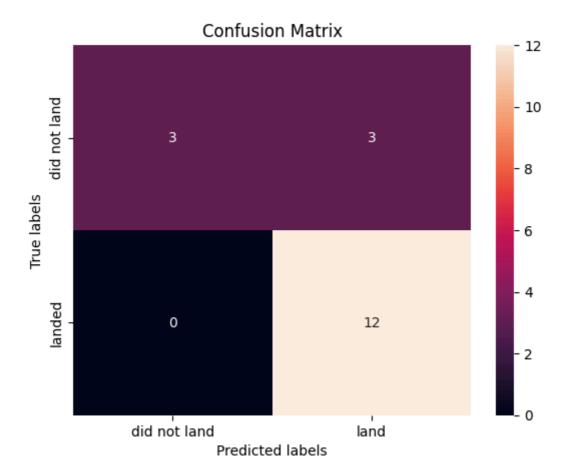

TASK 8

Create a decision tree classifier object then create a GridSearchCV object tree_cv with cv = 10. Fit the object to find the best parameters from the dictionary parameters.

```
'max_features': ['auto', 'sqrt'],
             'min_samples_leaf': [1, 2, 4],
             'min_samples_split': [2, 5, 10]}
        tree = DecisionTreeClassifier()
        tree_cv = GridSearchCV(tree, parameters, cv=10)
        tree_cv.fit(X_train, Y_train)
Out[ ]:
                   GridSearchCV
         ▶ estimator: DecisionTreeClassifier
             DecisionTreeClassifier
In [ ]:
In [ ]: print("tuned hpyerparameters :(best parameters) ",tree_cv.best_params_)
        print("accuracy :",tree_cv.best_score_)
        model_performance['tree'] = tree_cv.best_score_
       tuned hpyerparameters :(best parameters) {'criterion': 'gini', 'max_depth': 4,
       'max_features': 'sqrt', 'min_samples_leaf': 1, 'min_samples_split': 2, 'splitte
       r': 'random'}
       accuracy: 0.875
        TASK 9
        Calculate the accuracy of tree_cv on the test data using the method score:
In [ ]: tree = DecisionTreeClassifier(**tree cv.best params )
        tree.fit(X_train, Y_train)
```

```
In [ ]: yhat = tree.predict(X_test)
plot_confusion_matrix(Y_test,yhat)
```

TASK 10

Create a k nearest neighbors object then create a GridSearchCV object knn_cv with cv = 10. Fit the object to find the best parameters from the dictionary parameters.

```
In [ ]:
        parameters = {'n_neighbors': [1, 2, 3, 4, 5, 6, 7, 8, 9, 10],
                      'algorithm': ['auto', 'ball_tree', 'kd_tree', 'brute'],
                      'p': [1,2]}
        KNN = KNeighborsClassifier()
        knn_cv = GridSearchCV(KNN, parameters, cv=10)
        knn_cv.fit(X_train, Y_train)
Out[]:
                   GridSearchCV
         ▶ estimator: KNeighborsClassifier
               KNeighborsClassifier
In [ ]: X_test.shape
Out[]: (18, 83)
In [ ]: print("tuned hpyerparameters :(best parameters) ",knn_cv.best_params_)
        print("accuracy :",knn_cv.best_score_)
        model_performance['KNN'] = knn_cv.best_score_
```

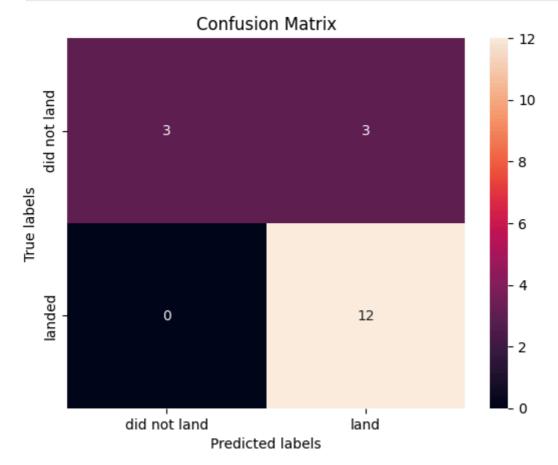

```
tuned hpyerparameters :(best parameters) {'algorithm': 'auto', 'n_neighbors': 1 0, 'p': 1} accuracy : 0.8482142857142858
```

TASK 11

Calculate the accuracy of knn_cv on the test data using the method score:

```
In [ ]: knn_cv.score(X_test, Y_test)
Out[ ]: 0.83333333333334

We can plot the confusion matrix
In [ ]: yhat = knn_cv.predict(X_test)
    plot_confusion_matrix(Y_test,yhat)
```

TASK 12

Find the method performs best:

```
In [ ]: sorted_model_performance = sorted(model_performance.items(), key=lambda item: it
    models = pd.DataFrame(sorted_model_performance, columns=['Model', 'Performance']
    models
```

Out[]:		Model	Performance
		0	tree	0.875000
		1	KNN	0.848214
		2	SVC	0.848214
		3	logreg	0.846429

The Decision Tree Claasifier model performs best.
